## Non-tangling moving-mesh methods for PDE problems in one and two dimensions II: problems with prescribed boundary fluxes

M.J.Baines

Department of Mathematics and Statistics, University of Reading, P.O.Box 220, Reading, RG6 6AX, UK

#### Abstract

Non-tangling moving-mesh algorithms based on local conservation for scalar PDE problems with prescribed boundary fluxes are derived in one and two dimensions, in the latter case on a linear simplex. Mesh tangling is prevented for any time step by applying an explicit signpreserving exponential time-stepping scheme to intervals in 1-D or edges/areas in 2-D. The nodes are found in a separate step respecting the integrity of the mesh.

## 1 Introduction

Moving-mesh methods for the approximate solutions of time-dependent partial differential equations (PDEs) are potentially more powerful than fixed mesh methods, capable of providing high resolution locally, sustaining scale invariance and propagating self-similarity [12, 8].

In the velocity-based conservation method of [1, 4, 16] a velocity field is determined from a local Eulerian conservation law which is used to deform the domain, finding the moved solution by local Lagrangian conservation. Applications can be found in [1, 2, 3, 4, 14, 17, 15, 16, 9, 5, 6, 10, 7, 18]. The method inherits the scale-invariance of the PDE problem, handles flux-driven moving boundary conditions, whether external or internal, in a natural way without the need for interpolation, and is capable of propagating self-similar scaling solutions at the nodes.

Numerically, the default time-stepping scheme has been explicit Euler. However, it is a requirement of the conservation method that the solution remains positive and the mesh untangled ,which in many cases demands a very small time-step, therefore limiting the practicality of the method.

In this paper a variant of the method is described which ensures a positive solution on an untangled mesh for any time step. This is achieved by applying a sign-preserving exponential time stepping scheme to intervals in 1-D and to edges or areas of a simplex in 2-D, with the nodal positions found a separate step.

The paper is organised as follows. In section 2 the relative conservation method is reviewed in one dimension, a semi-discrete scheme analysed, and a fully discrete version described that uses an explicit exponential timestepping scheme on interval lengths, leading to sign-preserving solutions on ordered meshes for any time step and culminating in the algorithms given in section 2.4.3.

In section 3 the two-dimensional conservation method is reviewed and the features described in 1-D generalised to 2-D on a simplex of triangles by applying the sign-preserving exponential time-stepping scheme to either edgelengths or triangle-areas. The nodes are found by an averaging procedure which retains the integrity of the simplex and solutions on the moved mesh obtained from relative Lagrangian conservation. The algorithms are given in section 3.3.5.

Conclusions are drawn in section 4.

## 2 The relative conservation method in 1-D

Suppose that the function u(x,t) satisfies the generic PDE

$$u_t = \mathcal{L}u,\tag{1}$$

in an interval (a(t), b(t)), where  $\mathcal{L}$  is a purely spatial operator, with given flux boundary conditions. Such problems occur for example in the study of nonlinear diffusion with evaporation, for example.

Define the total mass in the domain to be

$$\theta(t) = \int_{a(t)}^{b(t)} u(\xi, t) \,\mathrm{d}\xi \tag{2}$$

and intrduce a relative density function

$$\overline{u}(x,t) = \frac{u(x,t)}{\theta(t)} \tag{3}$$

satisfying

$$\int_{a(t)}^{b(t)} \overline{u}(\xi, t) \,\mathrm{d}\xi = 1 \tag{4}$$

from (2). By Leibnitz' Integral Rule the rate of change of the total mass  $\theta(t)$  is

$$\frac{\mathrm{d}\theta}{\mathrm{d}t} = \dot{\theta} = \frac{\mathrm{d}}{\mathrm{d}t} \int_{a(t)}^{b(t)} u(\xi, t) \,\mathrm{d}\xi = \int_{a(t)}^{b(t)} u_t \,\mathrm{d}\xi + \left[ u \frac{\mathrm{d}b}{\mathrm{d}t} \right] - \left[ u \frac{\mathrm{d}a}{\mathrm{d}t} \right] \tag{5}$$

which is known from (1) and the flux boundary conditions.

At any time t let the points x(t) of the domain (a(t), b(t)) move with velocity v(x, t) so as to satisfy the partial Lagrangian conservation law

$$\int_{a(t)}^{x(t)} \overline{u}(\xi, t) \,\mathrm{d}\xi = c(x), \text{ independent of } t, \tag{6}$$

consistent with (4) if c(b) = 1.

In an Eulerian form equivalent to the relative conservation law (6), the function  $\overline{u}(x,t)$  satisfies

$$\overline{u}_t + (\overline{u}v)_x = 0 = \frac{1}{\theta(t)}u_t - \frac{\dot{\theta}}{\theta(t)^2}u(x,t) + \frac{1}{\theta(t)}(uv)_x,\tag{7}$$

where v(x,t) is the Eulerian velocity and  $\dot{\theta}$  is given by (5). Thus, from equations (1), (7) and (3), at any time t the velocity v(x,t) satisfies the ODE

$$-\frac{\mathrm{d}}{\mathrm{d}x}(\overline{u}v) = -\frac{\dot{\theta}}{\theta(t)}u(x,t) + \mathcal{L}u \tag{8}$$

After integration from an anchor point, (taken to be a(t) without loss of generality) to a general point x, equation (8) yields

$$-\left(\overline{u}(x,t)v(x,t)\right)_{a(t)}^{x} = \int_{a(t)}^{x} \left(-\frac{\dot{\theta}}{\theta(t)}u(\chi,t) + \mathcal{L}u\right) \,\mathrm{d}\chi$$

using (3), so that

$$v(x,t) = v(a(t),t) + \frac{1}{u(x,t)} \frac{\dot{\theta}}{\theta(t)} \int_{a(t)}^{x} u(\chi,t) \,\mathrm{d}\chi - \frac{1}{u(x,t)} \int_{a(t)}^{x} \mathcal{L}(u) \,\mathrm{d}\chi \quad (9)$$

provided that u(x,t) > 0, in which v(x,t) = v(a(t),t) at x = a(t) (sufficient for uniqueness of v(x,t)). Using (6) we may simplify (9) to

$$v(x,t) = v(a(t),t) + c(x)\dot{\theta} - \frac{1}{u(x,t)} \int_{a(t)}^{x(t)} \mathcal{L}(u) \,\mathrm{d}\chi$$
(10)

## 2.1 A reference space

Introduce a Lagrangian moving coordinate  $\hat{x}(\xi, \tau)$ , where  $\xi$  is a fixed reference coordinate, such that

$$\frac{\partial \hat{x}}{\partial \tau} = \hat{v}(\xi, \tau), \qquad \tau = t,$$
(11)

where

$$\hat{v}(\xi,\tau) = v(\hat{x}(\xi,\tau),\tau)$$

By the chain rule

$$\widehat{v}(\xi,\tau) = v(\widehat{x}(\xi,\tau),\tau)$$

We consider two equations in the reference space. 1. Differentiating (11) with respect to  $\xi$ ,

$$\frac{\partial \widehat{x}_{\xi}}{\partial \tau} = \widehat{v}_{\xi} \tag{12}$$

from which the moving coordinate  $\widehat{x}(\xi,t)$  is retrieved from  $\widehat{x}_{\xi}$  using

$$\hat{x}(\xi,\tau) = \hat{x}_0 + \int_{\xi^0}^{\xi} \hat{x}_{\xi'} \,\mathrm{d}\xi'$$
(13)

2. The Lagrangian conservation form (6) transforms to

$$\frac{1}{\theta(\tau)}\widehat{u}(\xi,\tau)\left|\widehat{x}_{\xi}\right| = \widehat{c}(\xi), \text{independent of } \tau$$
(14)

for all  $\xi$ , where  $\hat{u}(\xi, \tau) = u(\hat{x}(\xi, \tau), \tau)$  and  $\hat{x}_{\xi}$  is the Jacobian of  $\hat{x}$  with respect to  $\xi$ . The sign of  $\hat{x}_{\xi}$  is determined by (12).

## 2.2 An initial value problem

Substitution of  $\hat{u}(\xi, \tau)$  from (14) into (12) yields an ODE system for  $\hat{x}_{\xi}$  and  $\theta(\tau)$ . Given initial conditions on  $\hat{x}$  and  $\hat{u}$  at  $\tau = \tau^0$  (and hence  $\hat{c}(\xi)$  together with (5), equations (12) and () then constitute an initial value problem for the two unknowns  $\hat{x}_{\xi}$  and  $\theta(\tau)$  possessing a unique solution under the conditions of Picard's Theorem.

From equation (12),

$$\frac{\partial \log \hat{x}_{\xi}}{\partial \tau} = \frac{\hat{v}_{\xi}}{\hat{x}_{\xi}} = v_x \tag{15}$$

since  $\hat{v}_{\xi}/\hat{x}_{\xi} = v_x$ . Integrating (15) from  $\tau^0$  to  $\tau$ , equation (15) has the formal solution

$$\widehat{x}_{\xi} = \widehat{x}_{\xi}^{0} \exp\left\{\int_{\tau^{0}}^{\tau} v_{x} \,\mathrm{d}\tau'\right\}$$
(16)

where  $\hat{x}_{\xi} = \hat{x}_{\xi}^{0}$  at  $\tau = \tau^{0}$ . The solution  $\hat{u}(\xi, \tau)$  on the moved domain is then generated from (14) by

$$\frac{1}{\theta(\tau)}\widehat{u}(\xi,\tau)\left|\widehat{x}_{\xi}\right| = \widehat{c}(\xi) = \frac{1}{\theta(\tau^{0})}\widehat{u}^{0}(\xi)\left|\widehat{x}_{\xi}^{0}\right|$$
(17)

where  $\hat{c}(\xi)$  is independent of  $\tau$  (therefore defined by the initial data), ensuring conservation of mass. The sign of  $\hat{x}_{\xi}$  is determined by the sign of  $\hat{x}_{\xi}^{0}$  from (16). The total mass  $\theta(\tau)$  is found by integration of  $d\theta/dt$  in (5).

The relative conservation method determines v (thus  $v_x$ ) from (10), obtains  $\hat{x}_{\xi}$  from (16) (thus  $\hat{x}$  from (13)),  $\theta(\tau)$  from (6), and finds  $\hat{u}$  from (17).

#### 2.2.1 Scale-invariance and self-similarity

If the PDE problem is scale-invariant such that the scaling transformation

$$t \to \lambda t', \quad \hat{x} \to \lambda^{\beta} x', \quad \hat{u} \to \lambda^{\gamma} u', \quad \theta \to \lambda^{\beta+\gamma} \theta'$$
 (18)

leaves the problem invariant [11], it is straightforward to verify that the solution of the initial value problem maintains the same scale invariance.

Self-similar scaling solutions are found by seeking an ansatz of the form

$$\widehat{x}(\xi,\tau) = \tau^{\beta}\xi, \qquad \widehat{u}(\xi,\tau) = \tau^{-\beta}\eta(\xi), \qquad \theta(\tau) = \tau^{\beta+\gamma}\vartheta$$
(19)

where  $\eta(\xi)$  satisfies an ODE derived from (1) and  $\vartheta$  is constant.

From (19),

$$\widehat{v}(\xi,\tau) = \frac{\partial \widehat{x}}{\partial \tau} = \beta \tau^{\beta-1} \xi$$

so that  $\hat{v}_{\xi} = \beta \tau^{\beta-1}$ , leading to  $v_x = \hat{v}_{\xi}/\hat{x}_{\xi} = \beta/\tau$ , independent of  $\xi$ . Hence, from (16) and (17),

$$\widehat{x}_{\xi} = \widehat{x}_{\xi}^{0} \exp\left\{\int_{\tau^{0}}^{\tau} (\beta/\tau') \mathrm{d}\tau'\right\} \quad \Rightarrow \quad \frac{\widehat{x}_{\xi}(\xi,\tau)}{\tau^{\beta}} = \frac{\widehat{x}_{\xi}(\xi,\tau^{0})}{(\tau^{0})^{\beta}}$$

$$\widehat{u}(\xi,\tau) = \frac{\widehat{c}(\xi}{|\widehat{x}_{\xi}|} \frac{\theta(\tau)}{\theta(\tau^0)} \widehat{u}^0(\xi) \exp\left\{-\int_{\tau^0}^{\tau} (\beta/\tau') \mathrm{d}\tau'\right\} \quad \Rightarrow \quad \frac{\widehat{u}(\xi,\tau)}{\tau^{\gamma}} = \frac{\widehat{u}(\xi,\tau^0)}{(\tau^0)^{\gamma}},$$

so that self-similar solutions are propagated iexactly n time.

Summarising, for PDEs of the form (1) with prescribed flux boundary conditions, the relative conservation method in the form presented here preserves the signs of  $\hat{x}_{\xi}$ ,  $\hat{u}$ , and  $\theta$ , is scale-invariant and propagates self-similar scaling solutions exactly in time.

We now consider a semi-discrete-in-time approximation by applying the procedure over a time step.

## 2.3 A semi-discrete-in-time scheme

Discretising the time variable  $\tau$  as  $\tau^n = n\Delta\tau$  where  $\Delta\tau$  is the time step and  $n = 0, 1, 2, \ldots$ , define

$$\widehat{x}^n(\xi) = \widehat{x}(\xi, \tau^n), \quad \widehat{x}^n_{\xi} = \widehat{x}_{\xi}(\tau^n), \quad \widehat{v}^n_{\xi} = \widehat{v}_{\xi}(\xi, \tau^n), \quad v^n_x = \widehat{v}^n_{\xi}/\widehat{x}^n_{\xi}$$

The velocity v remains equal to (10) and  $\hat{c}(\xi)$  is as in (14).

In the conservation-based scheme of [1, 4, 16] the moving coordinate  $\hat{x}^n(\xi)$  is advanced in time from equation (11) using the first-order-accurate explicit Euler scheme. While this scheme moves the nodes correctly to first order, there is no control over the positivity of  $\hat{x}_{\xi}$  (thus monotonicity of  $\hat{x}(\xi)$ ) and

the method can break down for a required time step. In this paper we use a modified time-stepping scheme, the sign-preserving exponential scheme applied to mesh intervals, which preserves the monotonicity of  $\hat{x}^n(\xi)$  and avoids node overtaking for any time step.

Approximating the integrand in (16) by its value at  $\tau^n$ , an explicit first-order-accurate exponential scheme for  $\hat{x}^n_{\xi}$  is

$$\hat{x}_{\xi}^{n+1} = \hat{x}_{\xi}^n \exp\{\Delta\tau \left(v_x\right)\}^n \tag{20}$$

The moving coordinate  $\hat{x}^{n+1}(\xi)$  is obtained at time step  $\tau^{n+1}$  using (13) in the form

$$\widehat{x}(\xi^{n+1}) = \int_{\xi^0}^{\xi^{n+1}} \widehat{x}_{\xi'} \,\mathrm{d}\xi' \tag{21}$$

where  $\xi^0$  is an anchor point necessary for uniqueness. From (20) the time evolution of  $\hat{x}_{\xi}$  is completely characterised by  $(v_x)^n$ .

Note that the scheme (20) preserves the sign of  $\hat{x}_{\xi}$  over a time step irrespective of  $\Delta \tau$  or  $(v_x)^n$ .

The scheme (20) may also be obtained by applying the first-order-accurate explicit Euler scheme to (15), i.e.

$$\log \hat{x}_{\xi}^{n+1} = \log \hat{x}_{\xi}^{n} + \Delta \tau (v_x)^n \tag{22}$$

The total mass  $\theta^{n+1}$  is found from the corresponding explicit exponential scheme

$$\theta^{n+1} = \theta^n \exp\{\Delta \tau \,\dot{\theta}^n / \theta^n\},\tag{23}$$

preserving its sign.

Equation (14) is time-independent and ensures that

$$\frac{1}{\theta^{n+1}}\hat{u}^{n+1}(\xi)\,|\hat{x}_{\xi}|^{n+1} = \frac{1}{\theta^n}\hat{u}^n(\xi)\,|\hat{x}_{\xi}|^n \tag{24}$$

yielding  $\hat{u}^{n+1}$ . The sign of  $(\hat{x}_{\xi})^{n+1}$  is determined by the sign of  $(\hat{x}_{\xi})^n$  in (20).

Once  $(v_x)^n$  has been found from (10), equation (20) (with (21)) determines  $\hat{x}^{n+1}(\xi)$ , equation (23) yields  $\theta^{n+1}$  and equation (24) gives  $\hat{u}^{n+1}(\xi)$ .

It is straightforward to verify that the scale invariance (18) is inherited from the PDE problem by the semi-discrete schemes (20) and (24). However, the argument in section 2.2.1 for the propagation of self-similar solutions no longer holds over a time step, since  $v_x$  is no longer proportional to  $1/\tau$ . Selfsimilar solutions are therefore propagated over a time step only to order  $\Delta \tau$ .

We now state the semi-discrete-in-time algorithm.

#### 2.3.1 A semi-discrete-in-time algorithm

#### Algorithm 1

At time  $\tau^n$ , given  $\hat{x}^n(\xi)$  and  $\hat{u}^n(\xi)$ , the semi-discrete algorithm is as follows.

At each time step

## Algorithm 1

- obtain  $v^n(x)$  from (10) and hence  $(v_x)^n$
- calculate  $\dot{\theta}$  from (5) and hence  $\theta^{n+1}$  from (23)
- determine  $\hat{x}_{\xi}^{n+1}$  from (20) and hence  $\hat{x}^{n+1}(\xi)$  from (21)
- deduce  $\hat{u}^{n+1}$  from (24)

The algorithm is sign-preserving in  $\hat{x}_{\xi}^{n}$ ,  $\hat{u}^{n}$  and  $\theta$  over a time step irrespective of  $\Delta t$  or the accuracy of  $v_{x}^{n}$ . It is conservative (a seen) by integration of (24) over the domain, inherits scale-invariance from the PDE problem, and propagates self-similar solutions over a time step to order  $\Delta \tau$ .

We now extend the algorithm to spatial approximation.

## 2.4 Spatial approximation

Suppose that at time level n the domain  $(a^n, b^n)$  is discretised using mesh points

$$a^n = \hat{x}_0^n < \hat{x}_1^n < \ldots < \hat{x}_N^n = b^n$$

with corresponding nodal solutions  $\hat{u}_i^n$  (i = 0, ..., N), and define

$$\widehat{x}_i^n = \widehat{x}^n(\xi_i), \quad \widehat{u}_i^n = \widehat{u}^n(\xi_i), \quad \widehat{v}_i^n = \widehat{v}^n(\xi_i),$$

Also let  $\delta(\cdot)_k$  denote the difference in the argument across an interval k. At the initial time, node-based  $\hat{u}_i^0$  and  $\hat{x}_i^0$  are obtained by sampling the initial data, while at later times  $\hat{u}_i$  and  $\hat{x}_i^n$  are given by the method itself.

In preparation we compute the approximate total mass  $\theta^n$  in the domain at time  $t^n$  from (2) using a composite trapezium rule, and determine  $\dot{\theta}^n$  in the same way from (5). Approximate relative masses  $\hat{c}_k$  (kept constant over the time step) are found in each interval k between points  $\hat{x}_i^n$  and  $\hat{x}_{i-1}^n$  from the trapezium rule

$$\widehat{c}_k = \frac{1}{\theta} \frac{1}{2} (\widehat{u}_i + \widehat{u}_{i-1}) (\widehat{x}_i - \widehat{x}_{i-1})$$

An approximate velocity  $v_i^n$  at each point  $\hat{x}_i^n$  is found from a composite trapezium rule approximation applied to (10). We approximate  $v_x$  in each interval k using finite differences as

$$(v_x)_k = \frac{(\delta v)_k}{(\delta \hat{x})_k}$$

#### 2.4.1 Fully discrete numerical schemes

Fully discrete forms of the schemes (20) and (24) are then

$$(\delta \hat{x}_k)^{n+1} = (\delta \hat{x}_k)^n \exp\{\Delta \tau (v_x)_k\},\tag{25}$$

and

$$\frac{1}{\theta^{n+1}} (\widehat{u}_k)^{n+1} \left| \delta \widehat{x}_k \right|^{n+1} = \frac{1}{\theta^n} (\widehat{u}_k)^n \left| \delta \widehat{x}_k \right|^n, \tag{26}$$

where  $\theta^{n+1}$  is given by (23) and  $\hat{u}_k$  is an interval-based value of  $\hat{u}$ , yet to be assigned to an end of the interval. The sign of  $(\delta \hat{x}_k)^{n+1}$  is determined by the sign of  $(\delta \hat{x}_k)^n$  in (25).

For problems where u(x,t) is specified at one boundary, the endpoint of the interval to which  $(\hat{u}_k)^{n+1}$  is assigned to the endpoint of the interval pointing away from that boundary. For problems in which u(x,t) is specified at both boundaries (26) is replaced by

$$\frac{1}{\theta^{n+1}} (\hat{u}_i)^{n+1} |\delta \hat{x}_{i-1/2} + \delta \hat{x}_{i+1/2}|^{n+1} = \frac{1}{\theta^n} (\hat{u}_i)^n |\delta \hat{x}_{i-1/2} + \delta \hat{x}_{i+1/2}|^n$$
(27)

for all interior nodes, yielding a node-based  $\hat{u}_i^{n+1}$  directly.

It follows from (25) and (26) or (27) that the signs of  $\delta \hat{x}_k$ ,  $\hat{u}_i$ , and  $\theta$  are preserved over a time step.

In order to obtain the node-based coordinate  $\hat{x}_i^{n+1}$  from the interval-based  $(\delta \hat{x})_k^{n+1}$  in (25) we use the discretised form of equation (21),

$$\hat{x}_{i\pm1}^{n+1} = \hat{x}_i^{n+1} \pm (\delta \hat{x}_{i\pm1/2})^{n+1}$$
(28)

When applied in successive intervals away from an anchor point  $\hat{x}_0$  (needed for uniqueness), equation (28) yields all the  $\hat{x}_i^{n+1}$  exactly. Since the signs of the  $\delta \hat{x}_k$  are preserved the  $\hat{x}_i$  remain ordered in a time step.

Another way of calculating the nodes  $\hat{x}_i$  from the intervals  $\delta \hat{x}_k$  with the same outcome as the recursive step (28) (one that we shall later generalise to 2-D) is to solve the set of equations

$$\frac{\widehat{x}_{i+1} - \widehat{x}_i}{\delta \widehat{x}_{i+1/2}} = \frac{\widehat{x}_i - \widehat{x}_{i-1}}{\delta \widehat{x}_{i-1/2}}$$
(29)

for all interior i (both sides equal to unity). Boundary conditions for (29) are either Neumann, imposed by setting the left or right hand side of (29) equal to unity, or Dirichlet, using node locations calculated from known boundary velocities. Equation (29) can be rewritten as the barycentric interpolant

$$\widehat{x}_{i} = \frac{(\delta \widehat{x}_{i-1/2})^{-1} \widehat{x}_{i-1/2} + (\delta \widehat{x}_{i+1/2})^{-1} \widehat{x}_{i+1/2}}{(\delta \widehat{x}_{i-1/2})^{-1} + (\delta \widehat{x}_{i+1/2})^{-1}}$$
(30)

for all interior i, its solution ensuring continuity when one of the  $\delta \hat{x}_{i\pm 1}$  is vanishingly small. The averaged position  $\hat{x}_i$  in (30) always lies between the midpoints of adjacent intervals so there can be no node overtaking.

Given  $(v_x)_k^n$ , equation (25) yields  $(\delta \hat{x}_i)^{n+1}$ , equation (23) gives  $\theta^{n+1}$ , and equations 28) or (30) lead to  $(\hat{x}_i)^{n+1}$ . The moved solution  $(\hat{u}_i)^{n+1}$  is given either by equation (26) (with assignment to an adjacent node) or equation (27) directly.

#### 2.4.2 Scale invariance and similarity

Equations (25), (23), (26), (27), and (28) inherit the scale invariance of the original problem.

In the case of a self-similar scaling solution the argument for the propagation of a self-similar scaling solution over a time step to order  $\Delta \tau$  relies on the approximation to  $v_x$  being independent of x. In the fully discrete meethod, although  $v_x$  is accurately represented by the discretisation, the temporal approximation remains of order  $\Delta \tau$ .

We now state the fully discrete algorithm.

#### 2.4.3 Fully discrete 1-D algorithm

#### Algorithm 2

At each time step  $\tau^n$ , given  $\hat{x}_i^n$  and  $\hat{u}_i^n$ ,

- obtain a discrete velocity  $\hat{v}_i^n$  from a numerical approximation of (10) and deduce  $(v_x)_k = (\delta \hat{v})_k / (\delta \hat{x})_k$
- calculate  $\dot{\theta}$  from (5) and hence  $\theta^{n+1}$  from equation (23)
- find  $(\delta \hat{x}_k)^{n+1}$  from (25) and hence  $\hat{x}_i^{n+1}$  from (28)
- determine  $(\hat{u}_k)^{n+1}$  from (26), then

(a) for problems in which u is given at one boundary only, assign  $u_k^{n+1}$  to  $\hat{u}_i^{n+1}$ , working away from the boundary where the condition is given, (b) for problems in which u is given at both boundaries, determine interior nodal values  $(\hat{u}_i)^{n+1}$  directly from (27).

The algorithm is order-preserving in  $\hat{x}_i$  and preserves the sign of  $\hat{u}_i$ .

In case (a) of the step determining  $\hat{u}^{n+1}$  it is conservative by summing (26) over all intervals, in the sense that

$$\left(\sum_{k} \widehat{u}_{k} \left|\delta \widehat{x}_{k}\right|\right)^{n+1} = \left(\sum_{k} \widehat{u}_{k} \left|\delta \widehat{x}_{k}\right|\right)^{n}$$
(31)

where  $\hat{u}_k$  is assigned to an endpoint of the k'th interval. In case of (b) it is conservative by summing (27) over all intervals, in the sense that

$$\left(\sum_{i} \widehat{u}_{i} \left|\delta\widehat{x}_{i-1/2} + \delta\widehat{x}_{i+1/2}\right|\right)^{n+1} = \left(\sum_{i} \widehat{u}_{i} \left|\delta\widehat{x}_{i-1/2} + \delta\widehat{x}_{i+1/2}\right|\right)^{n}$$
(32)

The algorithm is scale-invariant under the transformation (18), and propagates self-similar scaling solutions over a time step to order  $\Delta \tau$ .

## 2.5 1-D summary

Analytically, the method is sign-preserving in  $\hat{u}$ ,  $\theta$  and  $\hat{x}_{\xi}$  (therefore monotonicitypreserving in  $\hat{x}$ ) for arbitrary v. It is conservative, inherits scale invariance, and propagates self-similar solutions exactly in time.

In the semi-discrete-in-time case the algorithm of section 2.3.1 is explicit, first-order-in-time, and sign-preserving in  $\hat{u}$ ,  $\theta$ , and  $\hat{x}_{\xi}$  over a time step for arbitrary  $\Delta \tau$  and v. It is conservative, inherits scale-invariance, and propagates self-similar solutions over a time step to order  $\Delta \tau$ .

In the fully-discrete case the algorithm of section 2.4.3 is explicit, firstorder-in-time, non-tangling in  $\hat{x}_i$  and sign-preserving in  $\hat{u}_i$  over a time step for arbitrary  $\Delta t$  and  $v_x$ . The algorithm is conservative in the sense of (31) or (32), propagates a self-similar scaling solution to order  $\Delta \tau$ . The algorithm is conservative in a particular sense, inherits the scale invariance of the problem and propagates a self-similar scaling solution to order  $\Delta \tau$ . The algorithm is conservative in a particular sense, inherits the scale invariance of the problem and propagates a self-similar scaling solution to order  $\Delta \tau$ . The algorithm is conservative in a particular sense, inherits the scale invariance of the problem and propagates a self-similar scaling solution to order  $\Delta \tau$ .

Computations confirm the predictions of the theory.

As with any time-stepping scheme, temporal accuracy is undermined for large  $\Delta \tau$ . However, even if  $\Delta \tau$  is large and  $v_i$  inaccurate, in a time step the  $\hat{u}_i$  keeps the same sign and the  $\hat{x}_i$  remain ordered.

## 2.6 Oscillations

Although  $(\delta \hat{x})_k$  remains positive it is not necessarily monotonic and approximation errors may lead to spurious oscillations in  $v_x$  (see (22). By smoothing  $v_x$  we introduce extra numerical diffusion to counteract the oscillations at the expense of spatial accuracy.

The introduction of a Laplacian smoother,

$$\frac{1}{4}\left\{(v_x)_{k+1} + 2(v_x)_k + (v_x)_{k-1}\right\}$$

to  $(v_x)_k$  suppresses sawtooth oscillations in  $(v_x)_k$  and is equivalent to adding second order numerical diffusion. More than one application of the smoother may be required to render  $v_x$  monotonic and suppress the oscillations.

The positivity of the moved solution and the ordering of the mesh are unaffected by the smoothing.

## 3 The relative conservation method in 2-D

Suppose that the function  $u(\mathbf{x}, t)$  is a solution of the generic PDE

$$u_t = \mathcal{L}u, \tag{33}$$

in a moving domain  $\mathcal{R}(t)$ , where  $\mathcal{L}$  is a purely spatial operator, with given flux boundary conditions.

Define the total mass to be

$$\theta(t) = \int_{\mathcal{R}(t)} u(\boldsymbol{\xi}, t) \,\mathrm{d}\mathbf{x} \tag{34}$$

and introduce the relative density function

$$\overline{u}(x,t) = \frac{u(x,t)}{\theta(t)}$$

satisfying

$$\int_{\mathcal{R}(t)} \overline{u}(\boldsymbol{\xi}, t) \, \mathrm{d}\mathbf{x} = 1 \tag{35}$$

from (34). By the Reynolds Transport Theorem the rate of change of the total mass  $\theta(t)$  is

$$\frac{\mathrm{d}\theta}{\mathrm{d}t} = \dot{\theta} = \frac{\mathrm{d}}{\mathrm{d}t} \int_{\mathcal{R}(t)} u(\boldsymbol{\xi}, t) \,\mathrm{d}\mathbf{x} = \int_{\mathcal{R}(t)} u_t \,\mathrm{d}\mathbf{x} + \oint_{\partial\mathcal{R}(t)} \frac{\partial(uv)}{\partial n} \,\mathrm{d}S \qquad (36)$$

which is a known quantity from (33) and the normal flux boundary conditions.

At any time t let the points  $\mathbf{x}(t)$  of the domain  $\mathcal{R}(t)$  move with a velocity  $\mathbf{v}(\mathbf{x}, t)$  so as to satisfy the local Lagrangian conservation law

$$\int_{\Omega(t)} \overline{u}_t \, \mathrm{d}\mathbf{x} = c(\mathbf{x}), \text{ independent of } t \tag{37}$$

of the relative conservation law (35), consistent with (35) since  $c(\mathcal{R}) = 1$ .

Equivalently,  $\overline{u}(\mathbf{x}, t)$  satisfies the Eulerian form of the relative conservation law 37), i.e.

$$\overline{u}_t + \nabla \cdot (\overline{u}\mathbf{v}) = 0 = \frac{1}{\theta(t)}u_t - \frac{\dot{\theta}}{\theta(t)^2}u(\mathbf{x}, t) + \frac{1}{\theta(t)}\nabla \cdot (u\mathbf{v})$$
(38)

where  $\mathbf{v}(\mathbf{x}, t)$  is the Eulerian velocity, in which  $\dot{\theta}$  is given by (36) and  $\theta(t)$  by its integral. Then, from equations (33), (38) and (34), the velocity  $\mathbf{v}$  satisfies the time-independent PDE

$$-\nabla \cdot (u\mathbf{v}) = -\frac{\dot{\theta}}{\theta(t)} + \mathcal{L}u$$

in  $\mathcal{R}(t)$ .

For uniqueness put  $\mathbf{v} = \nabla \phi$ , where  $\phi(\mathbf{x}, t)$  is a velocity potential satisfying the Poisson equation

$$-\nabla \cdot (u\nabla\phi) = -\frac{\dot{\theta}}{\theta(t)} + \mathcal{L}u \tag{39}$$

For positive u equation (39) has a unique solution for  $\phi(\mathbf{x}, t)$  (and hence  $\mathbf{v}(\mathbf{x}, t)$ ) under suitable Dirichlet or Neumann boundary conditions on  $\phi$ .

## 3.1 A reference space

Introduce a Lagrangian moving coordinate  $\hat{\mathbf{x}}(\boldsymbol{\xi}, \tau)$ , where  $\boldsymbol{\xi}$  is a fixed reference coordinate and  $\tau = t$ , such that

$$\frac{\partial \widehat{\mathbf{x}}}{\partial \tau} = \widehat{\mathbf{v}}(\boldsymbol{\xi}, \tau) = \mathbf{v}(\widehat{\mathbf{x}}(\boldsymbol{\xi}, \tau), \tau)$$
(40)

Equation (40) cannot be differentiated in the same way as in (12) in 1-D since (11) is unidirectional, but we can obtain a multidimensional equivalent of (14).

The local Lagrangian conservation law (37) is expressed in terms of  $\boldsymbol{\xi}$  and  $\tau$  as

$$\frac{1}{\theta(t)}\widehat{u}(\boldsymbol{\xi},\tau) \left| J(\widehat{\mathbf{x}},\boldsymbol{\xi}) \right| = \widehat{c}(\boldsymbol{\xi}), \text{ independent of } t$$
(41)

where  $J(\hat{\mathbf{x}}, \boldsymbol{\xi})$  is the Jacobian of the transformation generated by (40), thus generalising (14). Given a function  $\hat{u}(\boldsymbol{\xi}, \tau)$  at any time  $\tau$ , equation (41) leads to a Monge-Ampere equation for a function  $\hat{\mathbf{x}}(\boldsymbol{\xi}, \tau)$ , using a different potential function [13].

In spite of the difficulties with generalisation of (40) and (41), if we specify that the 2-D mesh is a linear simplex we may build spatial approximations for edges and areas that allow us to take advantage of the 1-D properties.

## 3.2 Spatial approximation in 2-D

Let the time variable  $\tau$  be discretised as  $\tau^n = n\Delta \tau$ , n = 0, 1, 2, ..., where  $\Delta \tau$  is the time step, and define

$$\widehat{\mathbf{x}}_i^n = \widehat{\mathbf{x}}(\boldsymbol{\xi}_i, \tau^n), \quad \widehat{u}_i^n = \widehat{u}(\boldsymbol{\xi}_i, \tau^n), \quad \widehat{\mathbf{v}}_i^n = \widehat{\mathbf{v}}(\boldsymbol{\xi}_i, \tau^n)$$

In the conservation-based scheme of [1, 4, 16] the moving coordinate  $\hat{\mathbf{x}}_{i}^{n}$  is advanced in time from equation (40) using the first-order-accurate explicit Euler scheme. Although the nodes are moved in the correct direction to first order in time there is then no control over mesh tangling or positivity of the solution and the scheme may break down for required time steps. Instead, in this paper we use the explicit sign-preserving exponential scheme of section 2 which is sign-preserving and prevents node tangling in 1-D for any time step. There are two ways of doing this on a 2-D simplex, either through edge lengths or triangle areas.

## **3.3** Spatial discretisation on a 2-D simplex

Consider a 2-D simplex consisting of non-overlapping triangles of area  $A_k(\tau)$ , (k = 1, ..., K) and moving nodes  $\hat{\mathbf{x}}_i(\tau)$  with corresponding moved solution values  $\hat{u}_i(\tau)$ , (i = 1, ..., N).

We begin by deriving a finite volume approximation to the velocity potential  $\Phi_i(\tau)$  at the nodes of the simplex from (39) in the case where  $\mathcal{L}u = \nabla \cdot \mathbf{f}$ where  $\mathbf{f}$  is a flux function and g is a source term.

#### 3.3.1 Approximating the velocity potential

Assuming that  $\mathcal{L}u$  takes the form  $\nabla \cdot \mathbf{f} + g$  where  $\mathbf{f}$  is a flux function and g is a source term, in a finite volume approach by integrating (39) over the boundary of a patch of triangles  $\Pi_i$  surrounding node i,

$$\int_{\Pi_i} \nabla \cdot (u \nabla \phi) - \mathbf{f} \, \mathrm{d}\mathbf{x} = \int_{\Pi_i} \left( g + \frac{\theta}{\theta(t)} \right) \, \mathrm{d}\mathbf{x} \tag{42}$$

Using the divergence theorem equation (42) can be approximated by

$$\sum_{e_{ij}} \left\{ -\overline{u}_m \frac{(\Phi_j - \Phi_i)}{\delta \widehat{s}_{ij}} - f_n \right\} \overline{\delta s}_{ij} = \int \left( g + \frac{\dot{\theta}}{\theta(t)} \right) \, \mathrm{d}\mathbf{x} \tag{43}$$

where  $\Phi_i$  is the value of  $\phi$  sampled at the node  $\mathbf{x}_i$ ;  $e_{ij}$  is the edge joining node  $\mathbf{x}_i$  to node  $\mathbf{x}_j$ ;  $\overline{u}_m$  is the midpoint value of u on the edge  $e_{ij}$ ;  $f_n$  is the component of  $\mathbf{f}$  at  $\mathbf{x}_j$  in the direction from  $\mathbf{x}_i$  to  $\mathbf{x}_j$  and  $\overline{\delta s}_{ij}$  is the average of the lengths of the boundary edges opposite node  $\mathbf{x}_i$  either side of node  $\mathbf{x}_j$ .

The linear system consisting of (43) for all interior nodes is square and sparse and, given boundary conditions on  $\phi$  or  $\partial \phi / \partial n$ , is solved for the interor  $\Phi$  values by a standard method. Boundary conditions on  $\phi$  correspond to specifying tangential velocities and those on  $\partial \phi / \partial n$  to normal velocities.

#### 3.3.2 Approximating triangle velocities

Having found  $\Phi_i$  at the nodes, we calculate an approximation to the velocity  $\mathbf{V}_k$  in a triangle as the gradient of a piecewise linear function through  $\Phi_i$  values at the vertices. In a triangle k having values  $\Phi_1$ ,  $\Phi_2$ ,  $\Phi_3$  at vertices  $(x_1, y_1), (x_2, y_2), (x_3, y_3)$ , the velocity is

$$\mathbf{V}_{k} = (\nabla\Phi)_{k} = \frac{1}{2A_{k}} \left( \begin{vmatrix} 1 & 1 & 1 \\ \Phi_{1} & \Phi_{2} & \Phi_{3} \\ y_{1} & y_{2} & y_{3} \end{vmatrix}, \begin{vmatrix} 1 & 1 & 1 \\ x_{1} & x_{2} & x_{3} \\ \Phi_{1} & \Phi_{2} & \Phi_{3} \end{vmatrix} \right)_{k}$$
(44)

where  $A_k$  is the area of the triangle given by

$$A_{k} = \frac{1}{2} \begin{vmatrix} 1 & 1 & 1 \\ x_{1} & x_{2} & x_{3} \\ y_{1} & y_{2} & y_{3} \end{vmatrix}_{k}$$
(45)

#### 3.3.3 Approximating the nodal velocities

The velocities  $\mathbf{v}_i$  at the nodes are then obtained from the gradients  $\mathbf{V}_k = (\nabla \Phi)_k$  of  $\Phi$  in triangles k surrounding node i with areas  $A_k$  by the barycentric interpolant

$$\mathbf{v}_i = \frac{\sum_k A_k^{-1} V_k}{\sum_k A_k^{-1}} \tag{46}$$

where the sum is over all triangles k surrounding node i, having the property of continuity at a node when one of the  $A_k$  is vanishingly small.

Summarising the calculation of the nodal velocities, from the velocity potential  $\Phi$  given by (43) we obtain triangle-based velocities  $\mathbf{V}_k$  from (44) and node-based velocities  $\mathbf{v}_i$  from (46).

#### 3.3.4 Moving the nodes

In order to combat mesh tangling, instead of moving the nodes by the nodal velocities (46) directly, we update local edge lengths or triangle areas using their rates of change, enabling implementation of the sign-preserving properties of the explicit exponential time-stepping scheme seen in section 2.

#### Edge-length velocities

Consider an edge e of the simplex having a coordinate  $\hat{s}$  measured along the edge, and denote by  $\delta(\cdot)$  the difference in the argument along the edge (so that  $\delta \hat{s}$  is the length of the edge).

At each end of the edge define  $v_e$  to be the component of the velocity **v** at an end of the edge in the direction of the edge coordinate  $\hat{s}$ , and let  $\delta v_e$  be the difference between the two  $v_e$ 's at the endpoints of the edge.

Then the explicit exponential time-stepping scheme for updating the edge length  $\delta \hat{s}$  is

$$(\delta \hat{s})^{n+1} = (\delta \hat{s})^n \exp\left\{\Delta \tau \left(\delta V_e / \delta \hat{s}\right)\right\}^n, \tag{47}$$

which preserves the sign of the edge length  $\delta \hat{s}$  over a time step irrespective of  $\Delta \tau$  or  $\delta V_e / \delta \hat{s}$  (and therefore that of  $\hat{s}$ ).

Since all the edge lengths remain of the same sign, mesh tangling is avoided.

#### Triangle-area velocities

Alternatively, we can use triangles instead of edges. The rate of change of the triangle area  $A_k$ , given by (45) for a triangle with vertices  $(x_1, y_1)$ ,  $(x_2, y_2)$ ,  $(x_3, y_3)$ , is

$$\dot{A}_{k} = \left(\frac{\partial A}{\partial t}\right)_{k} = \frac{1}{2} \left\{ \begin{vmatrix} 1 & 1 & 1 \\ \overline{U}_{1} & \overline{U}_{2} & \overline{U}_{3} \\ y_{1} & y_{2} & y_{3} \end{vmatrix} + \begin{vmatrix} 1 & 1 & 1 \\ x_{1} & x_{2} & x_{3} \\ \overline{V}_{1} & \overline{V}_{2} & \overline{V}_{3} \end{vmatrix} \right\}_{k}$$
(48)

where  $(\overline{U}_1, \overline{V}_1), (\overline{U}_2, \overline{V}_2), (\overline{U}_3, \overline{V}_3)$  are the components of the vertex velocities  $\mathbf{v}_1, \mathbf{v}_2, \mathbf{v}_3$  in the two Cartesian coordinate directions.

Discretising (48) in time by the explicit exponential scheme, we obtain the update

$$A_k^{n+1} = A_k^n \exp\{\Delta t \, \dot{A}/A\}_k^n, \tag{49}$$

thus preserving the sign of  $A_k$  over a time step irrespective of  $\Delta t$  or  $(A)_k$  (and therefore  $\mathbf{V}_k$ ).

Since all the triangle areas remain of the same sign, mesh tangling is avoided.

The rate of change of the total mass  $\hat{\theta}$  is given by (5), then the total mass  $\theta^{n+1}$  obtained from the explicit exponential scheme

$$\theta^{n+1} = \theta^n \exp\{\Delta t \,\dot{\theta}^n / \theta^n\} \tag{50}$$

#### 3.3.5 Finding the node locations

It remains to locate the nodes from either the edge lengths or the triangle areas at the new time level  $\tau^{n+1}$ . Unlike in one dimension, there is no unique mesh that is consistent with given edge lengths or triangle areas, each problem being overdetermined in general.

We generalise the approach of (30) to 2-D using either edge-lengths or triangle-areas, as follows.

#### Edge-lengths

Suppose that the interior node  $\mathbf{x}_i$  of the simplex is connected to  $J_i$  nodes  $\mathbf{x}_i$ ,  $(j = 1, ..., J_i)$ , then generalisations of (29) and (30) to 2-D are

$$\sum_{j=1}^{J_i} \frac{(\widehat{\mathbf{x}}_m - \widehat{\mathbf{x}}_i)}{\delta \widehat{s}_{ij}} = 0 \quad \text{and} \quad \widehat{\mathbf{x}}_i = \frac{\sum_{j=1}^{J_i} (\delta \widehat{s}_{ij})^{-1} \widehat{\mathbf{x}}_m}{\sum_{j=1}^{J_i} (\delta \widehat{s}_{ij})^{-1}} \quad (51)$$

for all interior nodes  $\hat{\mathbf{x}}_i$ , where the  $\hat{\mathbf{x}}_m$  are the midpoints of the edges joining  $\hat{\mathbf{x}}_i$  to  $\hat{\mathbf{x}}_j$  and  $\delta \hat{s}_{ij}$  is the (positive) length of the edge connecting node *i* to node *j*. Positivity of the weights in the second of (51) ensures that  $\hat{\mathbf{x}}_i$  lies in the convex hull of the midpoints  $\hat{\mathbf{x}}_m$  of the edges through  $\hat{\mathbf{x}}_i$ , thus preventing tangling.

#### **Triangle-areas**

Similarly, if  $k = 1, ..., K_i$  denote triangles surrounding node  $\mathbf{x}_i$  with centroids  $\mathbf{x}_g$ , then generalisations of (29) and (30) are

$$\sum_{k=1}^{K_i} \frac{(\widehat{\mathbf{x}}_g - \widehat{\mathbf{x}}_i)}{A_k} = 0 \quad \text{and} \quad \widehat{\mathbf{x}}_i = \frac{\sum_{k=1}^{K_i} A_k^{-1} \widehat{\mathbf{x}}_g}{\sum_{k=1}^{K_i} A_k^{-1}} \quad (52)$$

where the  $A_k^{-1}$  are the (positive) inverse areas of the triangles surrounding node *i* (acting as spring constants). Positivity of the weights in the second of (52) ensures that  $\hat{\mathbf{x}}_i$  lies in the convex hull of the centroids  $\hat{\mathbf{x}}_g$  of the triangles containing  $\hat{\mathbf{x}}_i$ , also preventing tangling.

#### Boundary nodes

Boundary nodes are treated either as Dirichlet conditions by moving the nodes with the known boundary velocities  $\mathbf{v}_i$  of (46), or as Neumann conditions by applying modified forms of (51) or (52), as follows. In the case of edges, the boundary node equation (51) is modified to

$$\sum_{j=1}^{J_b} \frac{\widehat{\mathbf{x}}_m - \widehat{\mathbf{x}}_b}{\delta \widehat{s}_{bj}} = \sum_{j=1}^{J_b} \widetilde{\mathbf{e}}_j$$

where  $J_b$  is the number of edges emanating from boundary node b and  $\tilde{\mathbf{e}}_j$  is the unit vector from  $\mathbf{x}_b$  to  $\mathbf{x}_m$ , while in the case of areas the boundary node equation (52) is modified to

$$\sum_{k=1}^{K_b} \frac{\widehat{\mathbf{x}}_g - \widehat{\mathbf{x}}_b}{A_k} = \sum_{k=1}^{K_b} \widetilde{\mathbf{e}}_g$$

where  $K_b$  is the number of triangles k that contain the boundary node and  $\tilde{\mathbf{e}}_g$  is the unit vector from  $\hat{\mathbf{x}}_b$  to the centroid  $\hat{\mathbf{x}}_g$  of triangle k.

#### 3.3.6 Solving for the nodal positions

Because of the overlap of the patches each of the square sets of equations (51) or (52) leads to a sparse nonlinear matrix system for the  $\hat{\mathbf{x}}_i$ , which can be solved by standard methods, either direct or iterative.

An iteration for the second of (51) in the case of edges (where p is the iteration index) is

$$\widehat{\mathbf{x}}_{i}^{(p+1)} = \widehat{\mathbf{x}}_{i}^{(p)} + \left(\frac{\sum_{j=1}^{J_{i}} (\delta \widehat{s}_{ij})^{-1} (\widehat{\mathbf{x}}_{m} - \widehat{\mathbf{x}}_{i})}{\sum_{j=1}^{J_{i}} (\delta \widehat{s}_{ij})^{-1}}\right)^{(p)} = \left(\frac{\sum_{j=1}^{J_{i}} (\delta \widehat{s}_{ij})^{-1} \widehat{\mathbf{x}}_{m}}{\sum_{j=1}^{J_{i}} (\delta \widehat{s}_{ij})^{-1}}\right)^{(p)}, \quad (53)$$

while in the case of areas the second of (52) has the iteration

$$\widehat{\mathbf{x}}_{i}^{(p+1)} = \widehat{\mathbf{x}}_{i}^{(p)} + \left(\frac{\sum_{k=1}^{K_{i}} A_{k}^{-1}(\widehat{\mathbf{x}}_{g} - \widehat{\mathbf{x}}_{i})}{\sum_{k=1}^{K_{i}} A_{k}^{-1}}\right)^{p} = \left(\frac{\sum_{k=1}^{K_{i}} A_{k}^{-1}\widehat{\mathbf{x}}_{g}}{\sum_{k=1}^{K_{i}} A_{k}^{-1}}\right)^{(p)}$$
(54)

The solutions  $\hat{\mathbf{x}}_i$  of (51) or (52) (or their iterates  $\hat{\mathbf{x}}_i^{(p+1)}$  of (53) or (54)), together with the boundary node equations, lie in a non-overlapping subpatch (either the convex hull of midpoints of edges or the convex hull of centroids of surrounding triangles) of each patch, thus avoiding mesh tangling.

## 3.4 Finding the moved solution

Having obtained locations of the nodes at time  $\tau^{n+1}$ , the moved solution  $\hat{u}^{n+1}$  at these nodes is found from approximations to the Lagrangian conservation law (41), as follows.

#### From edges:

An approximate form of the Lagrangian conservation law (6) along an edge e is

$$\frac{1}{\theta^{n+1}} (\hat{u}_m \,\delta\hat{s}_e)^{n+1} = \hat{c}_e = \frac{1}{\theta^n} (\hat{u}_m \,\delta\hat{s}_e)^n \tag{55}$$

where m is the midpoint of the edge and  $\hat{c}_e$  is time-independent, leading to

$$(\widehat{u}_m)^{n+1} = \frac{\theta^{n+1}}{\theta^n} \frac{(\delta \widehat{s}_e)^n}{(\delta \widehat{s}_e)^{n+1}} \widehat{u}_m \tag{56}$$

where  $\theta^{n+1}$  is given by (50). The moved solution  $\hat{u}_i^{n+1}$  at the node  $\mathbf{x}_i$  is then the barycentric interpolant

$$\widehat{u}_{i}^{n+1} = \frac{\sum_{j=1}^{J_{i}} ((\delta s_{j})^{n+1})^{-1} \,\widehat{u}_{m}^{n+1}}{\sum_{j=1}^{J_{i}} ((\delta s_{j})^{n+1})^{-1}} \tag{57}$$

of the  $\hat{u}_m^{n+1}$  over those edges containing node  $\mathbf{x}_i$ , (cf. (29)), preserving the sign of  $\hat{u}_i^{n+1}$  and ensuring continuity of the  $\delta u_i^{n+1}$  when one of the  $(\delta s_j)^{n+1}$  is vanishingly small.

#### From areas:

An approximate form of the Lagrangian conservation (6) in a triangle k is

$$\frac{1}{\theta^{n+1}}(\widehat{u}_g A_k)^{n+1} = \widehat{C}_k = \frac{1}{\theta^n}(\widehat{u}_g A_k)^n \tag{58}$$

where  $\hat{C}_k$  is time-independent and  $\hat{u}_g$  is the value of  $\hat{u}$  at the centroid of triangle k, leading to

$$(\hat{u}_g)^{n+1} = \frac{\theta^{n+1}}{\theta^n} \frac{(A_k)^n}{(A_k)^{n+1}} (\hat{u}_g)^{n+1}$$
(59)

The moved solution  $\hat{u}_i^{n+1}$  at the node *i* is then the barycentric interpolant

$$\widehat{u}_{i}^{n+1} = \frac{\sum_{k=1}^{K_{i}} (A_{k}^{n+1})^{-1} \,\widehat{u}_{g}^{n+1}}{\sum_{k=1}^{K_{i}} (A_{k}^{n+1})^{-1}} \tag{60}$$

of the  $\hat{u}_g^{n+1}$  over triangles containing node  $\mathbf{x}_i$ , (cf.(29)), preserving the sign of  $\hat{u}_i^{n+1}$  and ensuring continuity of the  $\delta u_i^{n+1}$  when one of the  $(A_k)^{n+1}$  is vanishingly small.

## 3.5 Fully discrete 2-D algorithms

The 2-D algorithm for the solution of the PDE problem with prescribed flux boundary conditions on a simplex is as follows.

#### Algorithm 3

At each time step:

- 1. Determine the velocity potential at the nodes from (43) and the nodal velocities from (44) and (46),
- 2. advance the edge-lengths  $\delta s$  or triangle-areas A in time from (47) or (49), preserving their sign, and construct the nodes from (51) or (52),
- 3. calculate  $\theta^{n+1}$  from (50),
- 4. evaluate  $\hat{c}_e$  or  $\hat{C}_k$  from the right hand side of (55) or (58) and retrieve the solution on the moved mesh using (56) and (57) or (59) and (60).

Note that, due to the calculation of the nodes, the  $\hat{c}_e$  or  $\hat{C}_k$ , although held constant over a time step, are recalculated at the beginning if each step.

The algorithm is non-tangling in  $\hat{\mathbf{x}}_i$  and positivity-preserving in  $\hat{u}_i$ , irrespective of  $\Delta t$  or the accuracy of  $\nabla^2 \Phi$ . It is also conservative in the sense that, for edge lengths from (55),

$$\sum_{j} \widehat{u}_m \, \delta s_e$$

over all edges is constant over a time step, or for triangle areas, from (58),

$$\sum_{k} u_g A_k$$

over all areas is constant over a time step.

## 3.6 2-D summary

The difficulties in discretising the Lagrangian conservation law or in generating an untangled mesh when applying the velocity-based conservation method in 2-D are avoided by applying a sign-preserving time stepping scheme to edge lengths or triangle areas of a 2-D simplex to calculate positive updates, followed by their transfer to nodes by a projection, preserving the integrity of the simplex. The algorithm is explicit, first-order-in-time, sign preserving in  $\hat{u}_i$  and non-tangling in  $\hat{\mathbf{x}}_i$  for arbitrary  $\Delta t$  and  $\Phi$ .

Computations confirm the predictions of the theory.

## 3.7 Oscillations

Although there is no mesh tangling for any time step the edge-lengths or triangle-areas may not be sufficiently smooth spatially and numerical approximations may lead to spurious oscillations in the moved solution  $\hat{u}_i$  through oscillations in  $\nabla^2_{\mathbf{x}}\phi$ . By smoothing  $\nabla^2_{\mathbf{x}}\phi$  until it is monotonic, numerical diffusion can be introduced to counteract the oscillations. More than one application of the smoother may be required to suppress the oscillations.

The sign of the moved solution is preserved and the mesh remains untangled in a time step under second-order smoothing.

## 4 Conclusions

In this paper we have described a variant of the velocity-based relative conservation method for scalar PDEs with prescribed flux boundary ocnditions in one and two dimensions which, unlike the standard approach, ensures that the mesh remains untangled and the sign of the moved solution is preserved for any time step.

The essence of the paper is the replacement of the explicit Euler time stepping used in most implementations of the method by an explicit exponential time-stepping scheme, preserving the signs of moving intervals in 1-D or moving edge-lengths/triangle-areas on a simplex of triangles in 2-D. Transfer to nodes is by an additional step which preserves the integrity of the mesh.

We began in 1-D with an analysis of the relative conservation method, deriving the procedure from a mapping between fixed and moving domains and exhibiting the properties of exact propagation of scaling invariance and selfsimilarity. We then introduced discretisation in time, superseding the standard explicit Euler scheme by an explicit exponential time stepping scheme that preserves the monotonicity of the mesh and the sign of the solution, as well as keeping scale invariance and propagating self-similarity to first order in the time step Lastly we carried out spatial approximation using finite differences, applying the explicit exponential time stepping scheme to intervals rather than nodes, ensuring preservation of node-ordering and the sign of the solution. The nodes were retrieved uniquely from the intervals, either by a simple recurrence or by the solution of a second order equation. The fully discrete algorithm was stated in section 2.4.3.

In section 3 we reviewed the relative conservation method in 2-D in analytic form and highlighted the limitations in the numerical implementation of the method in higher dimensions. We then specialised the mesh to a 2-D simplex and applied the exponential time stepping scheme to the evolution of edge lengths and triangle areas using a projection to map these facets to the nodes without disturbing the integrity if the mesh, in this way generating a fully-discrete explicit method with a non-tangling mesh and a sign-preserving solution for any time step. The algorithm was stated in section 3.5.

Further work includes the generalisation of the approach to PDEs with general boundary conditions, to finite element approximation, and to three dimensions.
